Railway Alignment Design and Geometry

Track geometry is three-dimensional geometry of track layouts and associated measurements used in design, construction and maintenance of railroad tracks. The subject is used in the context of standards, speed limits and other regulations in the areas of track gauge, alignment, elevation, curvature and track surface. Although, the geometry of the tracks is three-dimensional by nature, the ...

Vertical alignment refers to the slope or grade of the railway, the rate of change of slope, and the vertical radius of crests and troughs. Grade AECOM13 Appendix 2B specifies a desirable gradient of 1.25% or below, a typical maximum of 2.5%, and an exceptional maximum of 3.5%.

It is very important for tracks to have proper geometric design in order to ensure the safe and smooth running of trains at maximum permissible speeds, carrying the heaviest axle loads. The speed and axle load of the train are very important and sometimes are also included as parameters to be considered while arriving at the geometric design of the track.

Basic Requirements of an Ideal Alignment 1. Purpose of the New Railway Line: The alignment of a new railway line should serve the basic purpose for which the railway line is being constructed. As brought out earlier, the purpose may include strategic considerations, political considerations, developing of backward areas, connecting new trade centres, and shortening existing rail lines.

What Rail alignment is the most important element of rail design. All other aspects of the design depend on it. As with any alignment, the design must also consider planimetric and high-ground information. Finding the best geometry helps you reduce cost, determine environmental impact, and allow for infrastructure such as bridges and tunnels, and retaining walls.

You can design a new rail
